(57) A developing apparatus usable with an image forming apparatus includes a frame having developing device; a toner accommodation container having an opening for supplying toner to the developing device and for accommodating the toner; and an elastic sheet inserted between the frame and the toner accommodation container to seal the opening, wherein the elastic sheet has a thickness larger than the gap when it is not compressed, and has a flexible sheet projected out of the gap. A method of sealing an opening of the toner accommodation container, includes detachably mounting an elastic sheet to a longitudinal end of an insertion member; then inserting the insertion member between the toner accommodation container and the frame to a position for sealing the opening by the elastic sheet; and then removing the elastic sheet from the insertion member. A sealing member for sealing an opening of a toner accommodating container includes a flexible film; and an elastic sheet on the flexible film.

FIG. 2

FIELD OF THE INVENTION AND RELATED ART

The present invention relates to a sealing member, a sealing member mounting method, a developing apparatus, a process cartridge, a process cartridge remanufacturing method and an image forming apparatus.

Electrophotographic type image forming machines are widely used as in copying machines or the like. In such an apparatus, a surface of an electrophotographic photosensitive drum which is rotated is uniformly charged, and a selective image exposure thereof is effected to form a latent image thereon. The latent image is visualized with toner and the toner image is transferred onto a recording material. In some of such apparatuses, a photosensitive drum and a developing device having a developer container or the like are unified into a cartridge, which is detachably mountable to an image forming apparatus. The latent image formed on the photosensitive drum is developed with developer contained in the developer container in the cartridge.

In order to prevent leakage of developer from the developer container during transportation of the process cartridge, an opening of the developer container with sealed by a sealing member. Prior to the start of use, the user removes the sealing member to open the opening of the container, by which the developer in the container is permitted to be supplied to the developing roller or the like through the opening of the container.

The present invention provides a further improvement in such an apparatus.

SUMMARY OF THE INVENTION

Accordingly, it is a principal concern of the present invention to provide a sealing member, a sealing member mounting method, a developing apparatus, a process cartridge, a process cartridge remanufacturing method and an image forming apparatus in which the sealing member is easily mountable.

Other features and advantages of the present invention will become more apparent upon a consideration of the following description of the preferred embodiments of the present invention taken in conjunction with the accompanying drawings, which are given by way of example.

BRIEF DESCRIPTION OF THE DRAWINGS

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to the accompanying drawings, first embodiment of the present invention will be described.

Embodiment 1

Figure 1 is a sectional view of an image forming apparatus loaded with a process cartridge, according to an embodiment of the present invention. Figure 2 is a sectional view of the process cartridge.

(General description)

The image forming apparatus A, as shown in Figure 1, projects light image bearing image information from an optical system 1 to a photosensitive drum which is an example of the image bearing member, and a developed image is formed on the photosensitive member. In synchronism with the toner image formation, the recording material 2 is fed by feeding means 3, and an image forming station which is in the form of a cartridge (process cartridge B), the toner image is transferred onto a recording material from the photosensitive drum by transfer means 4. The recording material 2 is fed to fixing means 5, where the toner image is fixed on the recording material, and the recording material is discharged to a discharge station.

A process cartridge B constituting the image forming station, as shown in Figure 2, is such that the photosensitive drum 7 is rotated while the surface thereof is uniformly charged by charging means 8, and the light image from the optical system 1 is projected onto the photosensitive drum 7 through the exposure station 9, so that a latent image is formed. The latent image is developed into a toner image by developing means 10. The toner image is transferred therefrom onto the recording material 2 by the transfer means 4, and thereafter, the residual toner remaining on the photosensitive drum 7 is removed by cleaning means. Various parts such as the photosensitive drum 7 or the like are mounted on a toner container 12a, developing device frame 12b and a cleaner frame 12c, and they are unified in the housing, so that they constitute a cartridge.

The description will be made as to various parts of the image forming apparatus A and the process cartridge B. The description will be further made as to a sealing member mounted to a toner container 12a around an opening thereof, and a mounting method therefor.

(Image forming apparatus)

The description will be made as to an optical system, feeding means, transfer means, fixing means and cartridge mounting means in this order.

(Optical system)

The optical system products the light beam carrying image information provided by an external apparatus or the like, onto the photosensitive member 7. As shown in Figure 1, it comprises an optical unit in the main assembly 1a containing a laser diode 1b, a polygonal mirror 1c, a scanner motor 1d and an image forming lens 1e.

When an image signal is sent from an external equipment such as a computer or word processor, the laser diode 1b emits light in response to the imaging signal, and the emitted light is projected as the imaging beam to the polygonal mirror 1c, which is being rotated at a high speed by a scanner motor 1d. The imaging beam reflected by the polygonal mirror 1c is projected through the image forming lens 1e and is effected by the mirror 1f onto the photosensitive drum 7, exposing selectively the surface thereof. As a result, a latent image is formed on the drum in accordance with the image information.

(Recording material feeding means)

The description will be made as to the structure of feeding means 3 for feeding the recording material (recording sheet, OHP sheet, cloth or thin sheet, for example).

The topmost sheet in cassette 3a is fed by a pick-up roller 3c and is fed to a registration roller pair 3c1 and 3c2. The registration roller pair is driven in synchronism with the image forming operation to feed the recording material 2 to an image transfer position.

The recording material 2 having received the toner image is fed to image fixing means 5 along a guide 3e by feed roller 3d, where the toner image is fixed. Then it is discharged to a discharge portion 6 by a discharging roller pair 3f with the record side facing down.

(Transfer means)

The transfer means 4 transfers the toner image formed on the photosensitive drum 7 onto a recording material. The transfer means 4 of this embodiment, as shown in Figure 1, is constituted by a transfer roller 4. By the transfer roller 4 the recording material 2 is pressed to the photosensitive drum 7 in the process cartridge B, while the transfer roller 4 is supplied with a voltage having a polarity opposite to that of the toner image formed on the photosensitive drum 7, so that the toner image is transferred onto a recording mate-

rial 2 from the photosensitive drum 7.

(Fixing means)

The fixing means 5 functions to fix the toner image having been transferred by the voltage applied to the transfer roller 4. As shown in Figure 1, the fixing means 5 comprises a driving roller 5a, and an inside heater 5b and a fixing roller 5c driven by the driving roller 5a by the press-contact therebetween. When the recording material having the toner image passes through a nip formed between the driving roller 5a and the fixing roller 5c, the pressure is applied by the nip between the rollers 5a and 5c, while being subjected to heat produced by the fixing roller 5c, by which the toner image is fixed on the recording material 2.

(Process cartridge mounting means)

In the image forming apparatus A, there is provided a cartridge mounting means for securely receiving the process cartridge B. As shown in Figure 3, the mounting or demounting of the process cartridge B relative to the main assembly 13 is effected after opening the opening member 14. The upper part of the main assembly 13 is provided with an opening member 14 operable by a hinge 14a. The opening member 14 is opened, and the cartridge is inserted along guides 36a and 36b into the cartridge receiving space in the main assembly 13. Then, the opening member 14 is closed, by which the process cartridge B is mounted to the image forming apparatus A.

(Process cartridge)

The description will be made as to the process cartridge B mounted to the image forming apparatus A.

This process cartridge B comprises an image bearing member and at least one processing means. As for the processing means, there are for example, a charging means for charging the surface of the image bearing member, a developing means for forming a toner image on the image bearing member, a cleaning means for cleaning the residual toner from the image bearing member surface, or the like. The process cartridge B of this embodiment comprises an electrophotographic photosensitive drum 7 as the image bearing member, a charging means 8, an exposure means 9, a developing means 10, and cleaning means 11, wherein the photosensitive drum 9 is surrounded thereby, as shown in Figure 2. These processing means are integrally contained in a housing 12 comprising a toner container 12a, a developing device frame 12b and a cleaner frame 12c, thus forming an exchangeable cartridge which can be loaded into or taken out of the main assembly of the apparatus.

The parts of the process cartridge B will be de-

scribed in the order of photosensitive drum 7, charging means 8, exposure means 9, developing means 10 and cleaning means 11.

5 (Photosensitive drum)

The photosensitive drum 7 in this embodiment comprises a drum base of cylindrical aluminum and an organic photoconductive layer applied thereon. 10 The photosensitive drum 7 is mounted rotatably on the cleaner frame 12c. A flange gear mounted to one longitudinal end of the drum 7 is driven by a driving force from a driving motor provided in the main assembly, by which the photosensitive drum 7 is rotated in a direction indicated by an arrow in Figure 2 in accordance with image forming operation. 15

(Charging means)

20 Charging means functions to uniformly charge the surface of the photosensitive drum 7, and in this embodiment, it is a so-called contact charging type in which a charging roller 8 is rotatably mounted on a cleaning container 12c. The charging roller 8 comprises a metal roller shaft 8a, an electroconductive elastic layer thereon, a high resistance elastic layer and a surface protection layer. The electroconductive elastic layer comprises a carbon dispersed in elastic rubber layer of EPDM or NBR or another elastic rubber layer. It is effective to introduce a bias voltage from the roller shaft 8a. The high resistance elastic layer is of urethane rubber or the like, and as an example, it contains a small amount of electroconductive fine powder. It is effective to limit leakage current to the photosensitive drum 7 to prevent sudden bias voltage drop even when the charging roller is contacted to a high electroconductivity portion such as a pin hole of the photosensitive drum 7. The protection layer is constituted by N-methylmethoxynylon, so that plastic material in the high resistance elastic layer or in the electroconductive elastic layer is directly contacted to the photosensitive drum 7 to deteriorate the surface of the photosensitive drum 7. 25 30 35 40

The charging roller 8 is contacted to the photosensitive drum 7, and for the image formation, the charging roller 8 is driven by the rotation of the photosensitive drum 7, and the superimposed application of the DC voltage and the AC voltage to the charging roller 8 is effective to uniformly charge the surface of the photosensitive drum 7. 45 50

(Exposure means)

The exposure station 9 is effective to expose the surface of the photosensitive drum 7 uniformly charged by the charging roller 8 to light image supplied from an optical system 1, thus forming an electrostatic latent image on the surface of the drum 7. An 55

opening 9a for introducing the light image formed in the top surface 37 of the housing 12 constitutes the exposure means 9.

(Developing means)

As shown in Figure 2, the developing means 10 comprises a toner container 12a for containing toner, and toner feeding member 10a rotatable to feed the toner. The developing device frame 12b mounted to an opening 12a1 side of the toner container 12a is provided with a developing sleeve 10c for forming thereon a thin toner layer with a non-rotatable magnet 10b therein.

When the toner layer is to be formed on the surface of the developing sleeve 10c, the toner and the developing sleeve 10d are contacted to triboelectrically charge the toner to a sufficient extent to develop the latent image on the photosensitive drum 7. In order to regulate the layer thickness of the toner, there is provided a blade 10d, as shown.

(Cleaning means)

The cleaning means 11, as shown in Figure 2, comprises a cleaning blade 11a for scraping toner off the drum 7 by contact to the surface thereof, a receptor sheet 11b disposed below the blade 11a lightly contacted to the surface of the photosensitive drum 7 to receive the toner scraped by the cleaning blade 11a, and a residual toner container 11c for containing the removed residual toner.

(Sealing structure for the toner container)

The description will be made as to a structure for sealing the opening 12a1 of the toner container 12a. In the process cartridge B, the sealing structure is different for a new or fresh cartridge than for a remanufactured cartridge which is to be used after use.

(Sealing structure for a fresh cartridge)

The opening 12a1 of the toner container 12a is sealed by a sealing member, so that the toner is prevented from leaking through the opening 12a1 during transportation of the cartridge B. As shown in Figure 13, an opening limiting member 15 for limiting the opening area is mounted to the opening 12a1 portion of the toner container 12a. In this embodiment, the opening 15a of the opening limiting member 15 is sealed by a sealing member 16.

By properly selecting the size of the opening 15a of the opening regulating member 15, the amount of the toner supplied from the toner container 12a to the developing sleeve 10c is regulated. The opening limiting member 15 is made of polyester plate, polystyrene plate, nylon plate, ABS plate or another plastic

plate having a thickness of approx. 0.3 - 2 mm, formed into a sheet. It is punched to provide the opening 15a. This is mounted to a flange 12a2 provided adjacent the opening 12a1 of the toner container 12a, by ultrasonic wave fusing or the like. The sealing member 16 of polyethylene film, polypropylene film or the like is heat-sealed to cover the opening 15a of the opening limiting member 15, and a free end 16a thereof is folded back.

As shown in Figure 4, the developing device frame 12b is coupled with the toner container 12a. The developing device frame 12b functions to support thereon a developing sleeve 10c or a developing blade 10d, and is provided with a rectangular opening 12b1 for permitting supply of the toner from the toner container 12a to the developing sleeve 10c. The opening limiting member 15 is fused to both of the long sides of the opening 12b1 by ultrasonic wave fusing or the like. The free end 16a of the sealing member 16 is exposed from one of short sides. In this manner, the toner container 12a and the developing frame 12b are fused to constitute non-separable developing unit 17. Upon the coupling between the developing device frame 12b and the toner container 12a, projections 12b of the developing frame 12b are engaged with holes 12a5 of the toner container 12a, so that the relative positional relationship therebetween is correctly established. By the unification of the toner container 12a and the developing device frame 12b by the use of the ultrasonic wave bonding, the toner leakage therebetween can be prevented, and it is desirable.

The long sides of the opening limiting member 15 and the developing frame 12b area fused, and therefore, there is no liability of toner leakage therebetween. However, the short sides are unable to be fused because pulling of the sealing member 16 has to be permitted. Therefore, slits is produced in the short sides, and therefore, there occurs a liability of the toner leakage. Therefore, end seal 18 is provided at each of the short ends of the developing frame 12b, so as to prevent the toner leakage.

When the process cartridge B sealed at the opening 15a is used, the operator pulls the free end 16a of the sealing member 16 exposed between the toner container 12a and the developing frame 16, prior to the mounting of the process cartridge B to the main assembly 13. Then, the sealing member 16 is peeled off the opening limiting member 15. This permits the toner to be supplied from the container 12a to the developing sleeve 10c.

Here, the new or fresh process cartridge means the one manufactured by fresh parts without using used parts, and a remanufactured process cartridge is the one manufactured at least partly with used parts or part, and toner is reloaded.

(Sealing structure for the remanufactured cartridge)

The description will be made as to the case in which a used cartridge is collected, and is disassembled, whereafter the toner is reloaded into the toner container 12a. First, disassembling process will be described, and the method of sealing the opening of the toner container 12a will be described.

As shown in Figure 5, for the process cartridge B, four pins 19 (2 at the left and 2 at the right) fixing the left and right wall portions 12d1 and 12d2 of the housing frame 12d on the developing unit 17 and the cleaning container 12c, are removed. Subsequently, as shown in Figure 5, left and right end portions of the housing frame 12d are gripped by hands (chain lines) in the manner that thumbs push down the top hatched portions and that remaining fingers urge outwardly the lower hatched portions (only one side is shown in Figure 5) of the left and right walls 12d1 and 12d2 of the housing frame 12d. Then, the upper part is raised, by which, as shown in Figure 6, the engagement between claws 12c1 on the top of the cleaning frame 12c and the engaging holes 12d3 of the housing frame 12d, are released, and therefore, the housing frame 12d is removed from the cleaning container 12c. The housing frame 12d is blown with air in an air duct so that foreign matters such as toner, dust and the like deposited on the outer or inner surfaces are removed to permit reuse.

Subsequently, as shown in Figure 7, springs 20 (only one spring is shown in Figure 7) which are disposed at the left and right ends of the developing device frame 12b and the cleaner frame 12c and which function to urge the developing sleeve 12c of the developing device frame 12b toward the photosensitive drum 7 in the cleaner frame 12c, is removed. Then, as shown in Figure 8, the connection of arms 21 threaded to the left and right ends of the developing frame 12b with the cleaning container 12c, is released. As a result of the series of disassembling operation, the developing unit 17 can be taken out.

Before disassembling the developing unit 17, it is first cleaned. In this cleaning, a cap 12a4 (Figure 12A) fixed to a toner supply port 12a3 (Figure 9) of the toner container 12a, for example, is removed, and a hose (not shown) connected with a sucking device (not shown) is inserted through the toner supply port 12a3 to suck out the toner remaining in the inside of the toner container 12a and the inside of the developing frame 12b.

After this cleaning, the developing unit 17 is disassembled. As shown in Figure 9, screws 22 is removed, and the developing blade 10d is removed. Further, the screws 23 at the left and right ends, are unthreaded, and the left and right arms 21 are pulled out. Then, the developing sleeve 10c and the magnet 10b mounted to the developing frame 12b are removed. Further, the developing sleeve 10c is dis-

sembled into parts. The parts are classified into reusable parts including a sleeve gear 24a, bearings 24b and the magnet 10b, and non-reusable parts to be replaced with fresh parts, including the developing sleeve 10c, a roller 24c and a sleeve electrode (not shown). The reusable parts are cleaned by air blow or the like.

As shown in Figure 10, the long side seal 25a, the short side seals 25b bonded by duplicated adhesive tape on the developing device frame 12b, and the film 25c at the bottom of the developing device frame 12b (chain lines in Figure 10), are removed. The adhesive material remaining on the developing frame 12b is removed, and thereafter, the cleaning is effected with the air or the like. Then, fresh long side seals 25a, the short side seals 25b and the film 25c are bonded by duplicated adhesive tapes, thus re-sealing the opening 12a1 of the toner container 12a.

The description will be made as to the re-sealing member for re-sealing the opening 12a1 and the toner container 12a and a re-sealing method.

The re-sealing member according to this embodiment is different from the sealing member 16 for a fresh cartridge. As shown in Figure 11A and Figure 11B, a flexible sheet or film 26b is adhered to an elastic sheet 26a by an adhesive or by duplicated adhesive tape 26c or the like. As for the material of the elastic sheet 26a, preferable materials include foamed urethane material, foamed polyethylene material, silicone rubber or the like. Among them, the foamed polyurethane material is particularly preferable because the permanent compression deformation is small, the sealing property is not deteriorated, and the sliding property is good. More particularly, a high density foamed polyurethane material having a hardness of 20 - 70 degrees, a permanent compression deformation of not more than 4 %, a friction coefficient of not more than 0.8, a cell size of 60 - 300 μ m, and a specific gravity of 0.2 - 0.5, is preferably used with 5 - 50 % compression. The high density foamed polyurethane is preferably Poron available from Inoac Corporation.

The preferable materials for the flexible sheet 26b include polyester, drawn polypropylene, nylon, polyethylene or the like. Among them, the polyester is particularly preferable because of the high tensile strength despite the small thickness thereof. The elastic material sheet 26a constitutes a main part of the re-sealing member 26. By the elastic compression deformation of the elastic sheet 26a, the opening is closed. The flexible sheet 26b also functions to reinforce the elastic sheet 26a to prevent tearing thereof when the user pulls the re-sealing member 26 prior to the start of use of the remanufactured cartridge. It extends to both of the long sides of the elastic sheet 26, and one side functions as an engagement when the re-sealing member 26 is inserted, and the other end functions as a grip 26b2 for pulling out the re-sealing

member 26.

The dimensions of the parts of the re-sealing members 26 are as follows:

elastic sheet 26a: L1 x L2 = 245 mm x 43 mm,
thickness t1 = 1 mm,

flexible sheet 26b: L3 x L4 = 445 mm x 43 mm,
thickness t2 = 0.1 mm.

As shown in Figure 12A, the re-sealing member 26 is inserted in a direction indicated by an arrow through a slit between the toner container 12a and the developing device frame 12b, while the opening 12a1 of the toner container 12a is faced down. In order to facilitate the insertion by reducing the insertion resistance of the re-sealing member 26 at this time, the re-sealing member 26 is sandwiched between a sliding sheet 26 and an insertion plate 29, as shown in Figure 12B. They are forcedly inserted through the slit 27.

The sliding sheet 26 may be of paper or plastic film coated with silicone or Teflon wax, for example, exhibiting good sliding property relative to the opening limiting member 15 and/or the developing frame 12b. The insertion plate 28 is preferably spring steel, stainless steel, for example, which is thin and is not easily bent.

The sliding sheet 28 used in this embodiment has a size of 445 mm x 43 mm and a thickness of 0.6 mm coated with silicone wax. The insertion plate 28 has a size of 300 mm x 40 mm, and a thickness of 0.2 mm made of spring steel. The gap t of the slit 27 is 1 mm.

The re-sealing member mounting method is as follows. As shown in Figure 12B, the sliding sheet 28 is overlaid on the elastic sheet 26a of the re-sealing member 26, and the flexible sheet 26b of the re-sealing member 26 is overlaid on the insertion plate 29. In other words, the re-sealing member 26 is interposed between the sliding sheet 28 and the insertion plate 29, and an engaging portion 26b1 of the flexible sheet 26b and the end portion of the sliding sheet 28 are folded back over an end of the insertion plate 29. With the state maintained, as shown in Figure 13A, they are inserted into the slit 27 with the sliding sheet 28 near the opening limiting member 15 and the insertion plate 28 near the developing device frame 12b.

The thickness of the elastic sheet 26a is larger than the slit gap, but the forced insertion using the insertion plate 29 compresses the elastic sheet 26a, and by the sliding property of the sliding sheet 28, the re-sealing member 26 is inserted through the slit 27 to between the opening limiting member 15 and the developing frame 12b.

As shown in Figure 13B, the inserting action is temporarily stopped immediately before the leading end of the insertion plate 29 reaches the end seal 18 and the rear side. Then, only the sliding sheet 28 is pulled out. This is because it becomes difficult to pull the sliding sheet 28 out after the sliding sheet 28 is inserted through the rear end seal 18.

As shown in Figure 13C, the leading end of the insertion plate 26 is projected out through the other end of the slit 27 to expose the engaging portion 26b1 of the flexible sheet 26b. Then, as shown in Figure 13D, the insertion plate 29 is pulled out. The grip 26b1 and the engaging portion 26b1 of the flexible sheet 26 are gripped, and the position of the re-sealing member 26 is adjusted so that the elastic sheet 26a completely covers the opening 15a of the opening limiting member 15. Finally, the portion of the engaging portion 26b1 of the flexible sheet 26b exposed to the outside beyond the slit 27 is cut out.

When the elastic sheet 26 completely covers the opening 15a, it is compressed between the opening limiting member 15 and the developing frame 12b, and therefore, it is completely close-contacted to the edges of the opening 15a, thus assuredly closing the opening 15a. Then, the toner does not leak to the developing device frame 12b even if the toner is refilled in the toner container 12a.

The toner is supplied through the toner supply port 12a3 into the toner container 12 having the opening 15a thus sealed, and the toner supply port 12a3 is capped with a cap 12a4. The developing sleeve 10c or the like are mounted through the steps which are reverse to the disassembling steps. Thus, the process cartridge B is remanufactured. For this remanufacturing, consumption parts mechanically worn, members having deteriorated performance, or parts requiring readjustment, or the like, are preferably exchanged or readjusted to recover the properties or performance thereof. As for the consumption parts, there are seals for preventing toner leakage or blade, and examples of performance deteriorated part includes the photosensitive drum.

The process cartridge thus remanufactured has the performance equivalent to that of the process cartridge. Upon the start of the use, the grip 26b2 of the flexible sheet 26b is pulled out, thus pulling the re-sealing member 26 out, by which the toner in the toner container 12a can be supplied into the developing sleeve 10c. The removed re-sealing member 26 is not contaminated with the adhesive material or the like, and therefore, is reusable.

Referring to Figures 14 - 15, a further embodiment will be described.

In this embodiment, a flexible sheet 26b is projected at one longitudinal end of the elastic sheet 26a, the projected portion functions as a grip 26b1 when the re-sealing member 26 is to be pulled out.

Therefore, the flexible sheet 26b is required to have a certain degree of tensile strength of approx. 2 kgf/15 mm - 40 kgf/15 mm under JIS K7113 plastic tensile test value.

Examples of various dimensions preferable for the re-sealing member 26 in this embodiment are as follows. In Figure 14, a length L1 of the elastic sheet 26a is approx. 220 - 240 mm; a width L2 is approx. 35

- 50 mm; a thickness t_1 is 0.5 - 2 mm. As for the flexible sheet 26b, a length L_3 is approx. 250 - 350 mm; a width L_4 is approx. 35 - 50 mm; and a thickness t_2 is 10 - 200 μm . In this embodiment, the elastic sheet 26a and the flexible sheet 26b are bonded by duplicated adhesive tape 26e, which has a thickness t_1 of 50 - 500 μm .

For reference, the sealing member 26 of this embodiment is the same as described hereinbefore having the dimensions of $L_1 = 235$ mm, $L_2 = 45$ mm, $t_1 = 0.8 - 0.9$ mm, $L_3 = 335$ mm, $L_4 = 45$ mm, $t_2 = 0.1$ mm and $t_3 = 0.15$ mm.

In this embodiment, the elastic sheet 26a and the flexible sheet 26b are bonded by the duplicated adhesive tape 26e. However, this is not limiting, and a bonding material or the like may be used. In this case, the thickness of the bonding layer is reduced as compared with the case of using the duplicated adhesive tape. In any case, the total thickness of the elastic sheet 26a and the flexible sheet 26b is larger than the gap of the slit 27.

The description will be made as to the process for mounting the re-sealing member 26 to the opening 12a1 of the toner container 12a by an operator.

As shown in Figure 15A, the re-sealing member 26 is inserted in a direction indicated by an arrow through a slit 27 formed between the toner container 12a and the developing device frame 12b, while the opening 12a1 of the toner container 12a is faced down. At this time, the sealing member 26 per se is not hard enough to be inserted to the sleeve 27, and therefore, an insertion plate 29 shown in Figure 12B is used. In order to improve the insertion operativity by reducing the insertion resistance, the use is made with a sliding sheet 28 to facilitate the forced insertion of the sheet member 26 into the slit 27.

Preferable dimensions of the insertion plate 29 in this embodiment are as follows. The length is approx. 275 - 400 mm, the width is approx. 40 - 45 mm, and the thickness is approx. 0.1 - 0.5 mm.

The size of the sliding sheet 28 is 685 mm x 43 mm and 0.6 mm in thickness. It is made of paper coated with silicone wax. The insertion plate 29 has a size of 350 mm x 40 mm, and a thickness of 0.2 mm, made of spring steel. The gap t of the slit 27 is 1 mm.

The mounting steps of the re-sealing member 26 will be described. As shown in Figure 15B, an end of the sliding sheet 26 is fixed using tape 30 at a longitudinal end (leading) of the insertion plate 29, and the sliding sheet 28 is folded back over the leading end of the insertion plate 29. On the other end of the insertion plate 29 (trailing end), a grip 26b1 of the flexible sheet 26b of the re-sealing member 26 is overlaid, and the gripping portion is fixed on the insertion plate 26 by a tape 30.

The sliding sheet 28 is long enough to be overlaid on the insertion plate 29 and the elastic sheet 26a of the sealing member 26. With this state, as shown in

Figure 13A, it is inserted into one end of the slit with the sliding sheet 28 near the opening limiting member 25 and the insertion plate 29 near the developing device frame 12b. In this embodiment, as shown in Figure 16A, the sliding sheet 28 is long enough to extend to the trailing edge of the elastic sheet 26a by way of the insertion plate 29, as a best example by which the friction resistance is reduced during the insertion. By doing so, the friction resistance upon the insertion of the sliding plate 29 and the elastic sheet 26a into the slit 27 can be reduced. However, the sliding sheet 28 is preferably long enough to cover a leading end 26a1 of the elastic sheet 26a bonded to the flexible sheet 26b. By doing so, the impact when the end 26a1 (Figure 15B) of the elastic sheet 26 abuts the slit 27 during the insertion, can be reduced. The use of the sliding sheet 28 is not inevitable if the materials of the insertion plate 29 and the elastic sheet 26a are properly selected, or if proper surface treatment is imparted.

In this embodiment, the flexible sheet 26b is bonded on one side of the insertion plate 29, and the sliding sheet 28 is bonded on the other side. In this example, the thickness of the insertion plate 29 and the thickness of the elastic sheet 26a are overlaid, and therefore, it is easy to insert the elastic sheet 26a. However, the present invention is not limited to this example. For example, the flexible sheet 26b may be bonded on the top surface of the insertion plate 29 shown in Figure 15B. By going so, a portion of the tape 30 for temporarily fixing the flexible sheet 26b on the insertion plate 29 is prevented from contact to the end seal 18. In the initial stage, the insertion plate 29 and the sliding sheet 28 are inserted into the slit 27 while they are overlaid, and as shown in Figure 16B, the leading end of the insertion plate 29 is projected out of the other end of the slit 27. At this time, the sealing member 26 is not yet inserted into the slit 27.

As the end of the insertion plate 29 projected out of the slit 27 is pulled out, as shown in Figure 16C, the sealing member 26 fixed by the tape to the end of the insertion plate 29 is inserted into the slit 27. The thickness of the sealing member 26 is larger than the gap of the slit 27, but by the forced pulling of the insertion plate 29 and the sliding property of the sliding sheet 28, the elastic sheet 26a is inserted into the slit 27 while being compressed.

As shown in Figure 16D, the insertion plate 29 is completely pulled out through the slit 27, so that the grip portion 26b1 of the flexible sheet 26b is projected out of the slit 27. By doing so, the elastic sheet 26a of the sealing member 26 is inserted between the opening limiting member 15 and the developing device frame 12b, and the opening 15a of the opening limiting member 15 is closed.

By the complete covering of the elastic sheet 26a for the opening 15a, it is completely closely contacted to the edge portions of the opening 15a since the elastic sheet 26a is compressed between the opening

limiting member 15 and the developing frame 12b. Thus, the opening 15a is assuredly sealed such that the toner does not leak to the developing frame 12b side even if the toner is supplied into the toner container 12a.

As shown in Figure 16E, the tape 30 fixing the sliding sheet 28 to the insertion plate 29 is removed, and only the sliding sheet 28 is pulled out of the slit 27. After the position of the sealing member 26 is adjusted, the tape 30 fixing the flexible sheet 26b on the insertion plate 29 is removed as shown in Figure 16F. Thus, the re-sealing is completed.

For the remanufacturing of the process cartridge B, the toner container 12a is refilled with the toner. For the refilling of the toner, there are a method in which the toner is supplied after the opening 15a is sealed by the sealing member 26, and a method in which the toner is supplied before the opening 15a is sealed.

In the case that the toner is supplied after the opening 15a is sealed, a cap 12a4 (Figure 16) covering the toner supply port 12a3 in the toner container 12a is removed. As shown in Figure 17, the toner is temporarily accommodated in the toner hopper 31 and is discharged by rotation of an auger 33 in an auger casing 32 at a bottom portion of the hopper 31. By controlling the number of screw rotations of the auger 33, the toner discharging speed can be easily controlled. The toner discharged by the rotation of the auger 33 is supplied into the toner container 12a having the opening 15a sealed by the sealing member 26, through a toner supply port 12a3 through the toner supplying funnel.

After the toner is supplied to the full of the toner container 12a, the toner supply port 12a3 is closed by a fresh cap 12a4, so that the toner refilling operation is completed.

When the toner is filled before the opening 15a is sealed, as shown in Figure 18, the toner container 12a before mounting the seal 26, is placed with the opening 15a faced up, and a toner supply nozzle 35 connected to a toner supplying machine (not shown) is placed in the opening 15a. The toner is discharged through the nozzle 35 to supply the toner into the toner container 12a. The nozzle 35 is reciprocated in the longitudinal direction of the opening 15a manually by the operator or automatically, thus filling the toner container 12a with the toner uniformly.

After the toner filling, the sealing member 26 is inserted into the slit 27 to seal the opening 15a.

When the toner is supplied the toner hopper 31 and the funnel 34 described above may be used. When the toner is supplied through the toner support port 12a3, the toner supply nozzle 35 may be used.

After the toner is refilled in the manner described above, the developing slit 10c or the like are mounted through the step reverse to the step for the disassembling, so that the process cartridge B can be remanufactured. For this remanufacturing, consumption

parts mechanically worn, members having deteriorated performance, or parts requiring readjustment, or the like, are preferably exchanged or refreshed to recover the properties or performance thereof. As for the consumption parts, there are seals for preventing toner leakage, and examples of performance deteriorated part includes the photosensitive drum. The parts to be reused are inspected by the operator's eyes or by machines, and only the parts satisfying a predetermined level, are used. Upon the start of the reuse of the remanufactured process cartridge, the sealing member 26 is pulled by gripping the grip 26b1 of the flexible sheet 26b, so that the toner in the toner container 12a may be supplied into the developing sleeve 10c.

(Further embodiment)

In the foregoing embodiment, the use is made with the sliding sheet 28 to improve the insertion operativity when the re-sealing member 26 is inserted into the slit 27. However, the use of the sliding sheet 28 is not inevitable if the material of the elastic sheet 26a of the re-sealing member 26 is properly selected, if the surface of the elastic sheet 26a is coated with a sliding layer. This is because the sliding property between the elastic sheet 26a and the opening limiting member 15 is improved. Therefore, there is no need of overlaying the sliding sheet 28, and the mounting of the re-sealing member 26 is made easier.

In the foregoing embodiment, the flexible sheet 26b is integrally mounted to prevent the elastic sheet 26a from being torn when the re-sealing member 26 is pulled out. However, the use of the flexible sheet 26b is inevitable if the material of the elastic sheet 26a is properly selected to use high tensile strength elastic sheet 26a. In this case, one end of the elastic sheet 26a is extended to be exposed out through the slit 27, to provide the gripping portion for the pulling.

In the foregoing embodiment, the opening limiting member 15 is fused on the edge of the opening of the toner container 12a, but the opening limiting member 15 is not inevitable if the size of the opening 12a1 of the toner container 12a is made equal to the opening 15a of the opening limiting member 15.

In the foregoing, the process cartridge B has been described as the cartridges for monochromatic image formation. However, the embodiments are suitably applicable to process cartridges for a multi-color image formation (two color image formation) three-color image formation or full-image formation or the like, by use of a plurality of developing means.

The image bearing member may have, as the photoconductor, zinc oxide, titanium oxide, amorphous silicon, organic photoconductor or the like. It may be in the form of a drum, belt or sheet or the like.

The usable developing methods include known two component magnetic brush development, cas-

cade development, touch-down development, cloud developing method or the like.

As for the charging means, the contact charging is used in the foregoing embodiment. However, another known method is usable in which a tungsten wire is enclosed at three sides with metal shield of aluminum or the like, and a high voltage is applied to the tungsten wire to produce and move positive or negative ions to the surface of the photosensitive drum, thus uniformly charging the surface of the drum.

In addition to a roller type charging member, it may be of blade type (charging blade), pad type, block type, rod type, wire type or the like.

As for the cleaning method for removing the residual toner from the photosensitive drum, a blade, a fur brush, magnetic brush or the like are usable.

The process cartridge described in the foregoing may contain an electrophotographic photosensitive member or the like as the image bearing member, and at least one of process means. For example, the image bearing member and the charging means is unified into a cartridge detachably mountable to a main assembly of the image forming apparatus. The image bearing member and the developing means are unified into a cartridge which detachably mountable to the main assembly. The image bearing member and the cleaning means are unified into a cartridge which is detachably mountable to the main assembly. The image bearing member and to or more of the process means, are unified into a cartridge, which is detachably mountable to the main assembly.

In other words, the process cartridge contains an electrophotographic photosensitive member and at least one of charging means, developing means and cleaning means. The cartridge is detachably mountable to relative to the main assembly of the image forming apparatus. As an example, at least the developing means and the electrophotographic photosensitive member are unified into a cartridge.

In the foregoing description, the image forming apparatus is in the form of a laser beam printer, but the present invention is not limited to this. For example, it is applicable to an LED printer, an electrophotographic copying machine, a facsimile machine, word processor or the like.

As described in the foregoing, according to the embodiments of the present invention, the elastic sheet is inserted between the developer container and the developing device frame, by which the elastic sheet is compressed and deformed to be closely contacted to the edge portions of the developer container, and therefore, the opening of the developer container to be reused is sealed by the elastic sheet. By refilling the developer container with the developer, the cartridge can be reused.

For the insertion of the sealing member, the insertion member and the sealing member are not inserted between the developer container and the de-

veloping frame while being overlapped with each other, and therefore, the force required for insertion is small, and there is no liability of the damage for the end seals for preventing the toner leakage.

When the sealing member is inserted, it is inserted from one side, and is pulled from the other side, therefore, the insertion member is moved in one way. Therefore, the insertion operativity is improved, and an automatic assembling is possible.

As described in the foregoing, the elastic sheet is compressed and deformed to press-contact to the edge of the opening of the developer container so that the opening of the developer container to be reused is sealed by the elastic sheet. By refilling the developer accommodation container with the developer, the process cartridge can be reused.

While the invention has been described with reference to the structures disclosed herein, it is not confined to the details set forth and this application is intended to cover such modifications or changes as may come within the purposes of the improvements or the scope of the following claims.

Claims

1. A sealing member for sealing an opening of a toner accommodating container, comprising:
a flexible film; and
an elastic sheet on said flexible film.
2. A sealing member according to Claim 1, wherein said flexible film is of polyester, drawn polypropylene, nylon or polyethylene material.
3. A sealing member according to Claim 1 or 2, wherein said flexible film has a thickness of approx. 10 - 200 μ m.
4. A sealing member according to Claim 1, wherein said flexible film has a width of approx. 35 - 50 mm.
5. A sealing member according to Claim 1, wherein said flexible film has a length of approx. 220 - 350 mm.
6. A sealing member according to Claim 1 or 3, wherein said flexible film has a tensile strength of approx. 2 kgf/15 mm - 40 kgf/15 mm under JIS K7113.
7. A sealing member according to Claim 1, wherein said elastic sheet is of foamed polyurethane, foamed polyethylene or silicone rubber.
8. A sealing member according to Claim 1 or 2, wherein said elastic sheet has a thickness of ap-

prox. 0.5 - 2mm.

9. A sealing member according to Claim 1, wherein said elastic sheet has a width of approx. 30 - 50 mm.

5

10. A sealing member according to Claim 1, wherein said elastic sheet has a length of approx. 220 - 240 mm.

10

11. A sealing member according to Claim 1, wherein said elastic sheet is so flexible that it is unable to be inserted into a gap by itself.

12. A sealing member according to Claim 1, 6 or 8, wherein said elastic sheet is bonded on said flexible sheet by an adhesive material or by a duplicated adhesive tape.

15

13. A sealing member according to Claim 1 or 13, wherein said elastic sheet extends over an entire width of said flexible sheet at an end of said flexible sheet.

20

14. A sealing member according to Claim 1 or 3, wherein the other end of said flexible sheet is temporarily fixed on a metal plate, and an end of the metal plate opposite from the temporarily fixed end, a sliding sheet is temporarily fixed.

25

30

15. A sealing member according to Claim 1 or 3, wherein said elastic sheet is of a high density foamed polyurethane material having a hardness of 20 - 70 degrees, a compression permanent deformation of 4 % or lower, a friction coefficient of 0.8 or lower, a cell size of 60 - 300 μ m, a specific gravity of 0.2 - 0.5, which is compressed by 5 - 50 %.

35

16. A sealing member according to Claim 1, wherein said sealing member is inserted between the toner accommodating container and a developing device frame to seal an opening of the toner accommodation container.

40

45

17. A method of sealing an opening of the toner accommodation container, comprising the steps of:
detachably mounting an elastic sheet to a longitudinal end of an insertion member; then
inserting the insertion member between the toner accommodation container and the frame to a position for sealing the opening by the elastic sheet; and then
removing the elastic sheet from said insertion member.

50

55

18. A method according to Claim 17, wherein said insertion member is of stainless steel, steel or cop-

per.

19. A method according to Claim 17 or 18, wherein the insertion member has a thickness of approx. 0.1 - 0.5 mm.

20. A method according to Claim 17, wherein said insertion member has a width of approx. 40 - 45 mm.

21. A method according to Claim 17, wherein said insertion member has a length of approx. 275 - 400 mm.

22. A method according to Claim 17, wherein said insertion member is an elastic plate having a rigidity sufficient for insertion between the toner accommodation container and the frame.

23. A method according to Claim 17 or 19, further comprising the step of mounting the elastic sheet on the flexible sheet, wherein when the elastic sheet is detachably mounted at one longitudinal end of the insertion member, an end of the flexible sheet is mounted to an end of the insertion member.

24. A method according to Claim 17 or 23, further comprising mounting the elastic sheet on the flexible sheet, wherein when the elastic sheet is introduced to the sealing position, a part of the flexible sheet is projected from a gap between the toner accommodation container and the frame, and the projected portion may be gripped by a user when the elastic sheet is to be pulled out.

25. A method according to Claim 17 or 24, further comprising detachably mounting a sliding sheet to the other longitudinal end of the insertion member, wherein when the insertion member is inserted into a gap between the toner accommodation container and the frame, the elastic sheet and the sliding sheet are overlaid.

26. A method according to Claim 25, wherein the sliding sheet is of paper or plastic film coated with silicone wax or Teflon wax.

27. A method according to Claim 17, wherein said frame is provided with a mount for mounting a developing sleeve.

28. A method according to Claim 17, wherein prior to sealing an opening of the toner accommodation container, toner is supplied into the toner accommodation container.

29. A method according to Claim 17, wherein after an opening of the toner accommodation container is sealed, the toner is supplied into the toner accommodation container.

30. A method according to Claim 17, wherein the toner accommodation container is unified with developing means and an image bearing member to constitute a process cartridge detachably mountable to a main assembly of an image forming apparatus.

31. A developing apparatus usable with an image forming apparatus comprising:
a frame having developing means;
a toner accommodation container having an opening for supplying toner to said developing means and for accommodating the toner; and
an elastic sheet inserted between said frame and said toner accommodation container to seal the opening, wherein said elastic sheet has a thickness larger than the gap when it is not compressed, and has a flexible sheet projected out of the gap.

32. An apparatus according to Claim 31, wherein said elastic sheet has a thickness of approx. 0.5 - 2 mm.

33. A method of remanufacturing a process cartridge detachably mountable to a main assembly of an image forming apparatus, comprising the steps of:

disassembling said process cartridge into a first frame having an image bearing member and a second frame having a toner accommodation container for accommodating toner, said toner accommodation container having a developing means frame having developing means and an opening for supplying toner to said developing means;

supplying toner into the toner accommodation container;

mounting an elastic sheet to one longitudinal end of an insertion member;

sealing the opening by the elastic sheet by inserting the insertion member into a gap formed between the toner accommodation container and the developing means frame;

removing the elastic sheet from the insertion member;

coupling the first frame and the second frame.

34. A method according to Claim 33, wherein said mounting step, sealing step and removing step are carried out prior to said toner supplying step.

35. A method according to Claim 34, wherein said toner supplying step, the toner is supplied through a supply opening, and after the toner is supplied, the supply opening is capped.

36. A method according to Claim 33, wherein said toner supplying step is carried out prior to said mounting step, said sealing step and said removing step.

37. A process cartridge detachably mountable to a main assembly of an image forming apparatus, comprising:

an image bearing member;

developing means having a frame; toner accommodation container, having an opening for supplying toner to said developing means, for accommodating toner; a toner accommodation container having an opening for supplying toner to said developing means and for accommodating the toner; and an elastic sheet inserted between said frame and said toner accommodation container to seal the opening, wherein said elastic sheet has a thickness larger than the gap when it is not compressed, and has a flexible sheet projected out of the gap.

38. A process cartridge according to Claim 37, further comprising cleaning means.

39. A process cartridge according to Claim 37 or 38, further comprising charging means.

40. An image forming apparatus usable with a process cartridge detachably mountable thereto, comprising:

means for mounting a process cartridge, said cartridge having an image bearing member; developing means having a frame; a toner accommodation container, having an opening for supplying toner to said developing means, for accommodating the toner; a toner accommodation container having an opening for supplying toner to said developing means and for accommodating the toner; and an elastic sheet inserted between said frame and said toner accommodation container to seal the opening, wherein said elastic sheet has a thickness larger than the gap when it is not compressed, and has a flexible sheet projected out of the gap;

mounting means for detachably mounting said process cartridge;

feeding means for feeding a recording material on which an image is formed.

41. A method of sealing an opening of a developer container for containing a developer or image formation, wherein between a developer container

- having a developing frame at an opening thereof and said developing frame, an elastic sheet having a thickness larger than a gap between said developer container and said developing frame is inserted to seal the opening of said developing container.
42. A method according to Claim 42, wherein said elastic sheet is integral with a flexible film.
43. A method according to Claim 41 or 42, wherein said elastic sheet is inserted between said developer container and said developing frame, using an insertion plate.
44. A method according to Claim 41 or 43, wherein a sliding sheet is overlaid on said elastic sheet, and said elastic sheet and said sliding sheet are integrally inserted between said developer container and said developing frame, and thereafter, said sliding sheet is pulled out to seal the opening of said developer container.
45. A developing apparatus for supplying developer for image formation, comprising:
 a developer container having a developer accommodating portion for accommodating a developer and an opening for supplying the developer;
 a developing frame mounted to the opening of said developer container for mounting a developing member;
 an elastic sheet having a thickness larger than a gap between said developer container and said developing frame; and
 wherein said elastic sheet is inserted between said developer container and said developing frame to seal the opening of said developer container.
46. An apparatus according to Claim 45, wherein said elastic sheet is integral with said flexible film.
47. A developing apparatus according to Claim 45 or 46, wherein said opening of said developer container is opened by pulling a free end of said elastic sheet or said flexible sheet to permit the developer in said developer container to be supplied to said developing member.
48. A developing apparatus according to Claim 45 or 47, wherein said elastic sheet is of foamed polyurethane, foamed polyethylene or silicone rubber.
49. An apparatus according to Claim 46, wherein said flexible film is of polyester, drawn polypropylene, nylon or polyethylene material.
50. A process cartridge detachably mountable to a main assembly of an image forming apparatus, comprising:
 an image bearing member;
 a developing apparatus including a developer accommodating portion for accommodating a developer, a developer container having an opening for supplying the developer, a developing frame, mounted to the opening of said developer container, for mounting a developing member, an elastic sheet having a thickness larger than a gap between said developer container and said developing frame, wherein said elastic sheet is inserted between said developer container and said developing frame to seal the opening of said developer container.
51. A process cartridge according to Claim 50, further comprising charging means.
52. A process cartridge according to Claim 50 or 51, further comprising cleaning means.
53. An image forming apparatus usable with a process cartridge detachably mountable thereto, comprising:
 mounting means for mounting the process cartridge, said process cartridge having an image bearing member; a developing apparatus including a developer accommodating portion for accommodating a developer, a developer container having an opening for supplying the developer, a developing frame, mounted to the opening of said developer container, for mounting a developing member, an elastic sheet having a thickness larger than a gap between said developer container and said developing frame, wherein said elastic sheet is inserted between said developer container and said developing frame to seal the opening of said developer container;
 means for feeding a recording material on which an image is formed by said image forming apparatus.
